

# Structural Testing

Software Engineering  
Andreas Zeller • Saarland University

1

## Testing Tactics

Functional  
“black box”

Structural  
“white box”

- Tests based on *spec*
- Test covers as much *specified* behavior as possible
- Tests based on *code*
- Test covers as much *implemented* behavior as possible

2

In contrast to *functional tests* (discussed the last time), *structural* tests are based on the code structure

## Why Structural?

Functional  
“black box”

Structural  
“white box”

- If a part of the program is never executed, a defect may loom in that part  
A “part” can be a statement, function, transition, condition...
- Attractive because automated

3

Structural tests are automated – and can be much more fine-grained than functional tests.

# Why Structural?

- **Complements functional tests**  
Run functional tests first, then measure what is missing
- **Can cover low-level details missed in high-level specification**

4

Recall this example from last lecture.

## A Challenge

```
class Roots {  
    // Solve  $ax^2 + bx + c = 0$   
    public roots(double a, double b, double c)  
    { ... }  
  
    // Result: values for x  
    double root_one, root_two;  
}
```

- **Which values for  $a, b, c$  should we test?**  
assuming  $a, b, c$ , were 32-bit integers, we'd have  $(2^{32})^3 \approx 10^{28}$  legal inputs  
with 1.000.000.000.000 tests/s, we would still require 2.5 billion years

5

## The Code

```
// Solve  $ax^2 + bx + c = 0$   
public roots(double a, double b, double c)  
{  
    double q = b * b - 4 * a * c;  
    if (q > 0 && a != 0) {  
        // code for handling two roots  
    }  
    else if (q == 0) {  
        // code for handling one root  
    }  
    else {  
        // code for handling no roots  
    }  
}
```

$$x = \frac{-b \pm \sqrt{b^2 - 4ac}}{2a}$$

Test this case

and this

and this!

6

If we know the code (“white box”) and thus the structure, we can design test cases accordingly

# The Test Cases

```
// Solve  $ax^2 + bx + c = 0$ 
public roots(double a, double b, double c)
{
    double q = b * b - 4 * a * c;
    if (q > 0 && a != 0) {
        // code for handling two roots
    }
    else if (q == 0) {
        // code for handling one root
    }
    else {
        // code for handling no roots
    }
}
```

$$x = \frac{-b \pm \sqrt{b^2 - 4ac}}{2a}$$

(a, b, c) = (3, 4, 1)

(a, b, c) = (0, 0, 1)

(a, b, c) = (3, 2, 1)

7

Finding appropriate input values is a challenge in itself which may require external theory – but in this case, the external theory is just maths.

# A Defect

```
// Solve  $ax^2 + bx + c = 0$ 
public roots(double a, double b, double c)
{
    double q = b * b - 4 * a * c;
    if (q > 0 && a != 0) {
        // code for handling two roots
    }
    else if (q == 0) {
        x = (-b) / (2 * a);
    }
    else {
        // code for handling no roots
    }
}
```

$$x = \frac{-b \pm \sqrt{b^2 - 4ac}}{2a}$$

(a, b, c) = (0, 0, 1)

code must handle a = 0

8

The test case that executes the q = 0 branch reveals a defect – the case a = 0

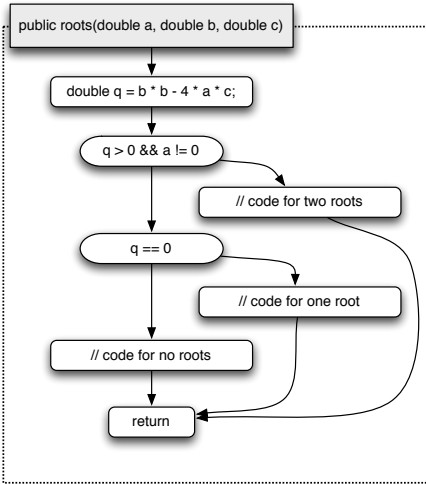

# Expressing Structure

```
// Solve  $ax^2 + bx + c = 0$ 
public roots(double a, double b, double c)
{
    double q = b * b - 4 * a * c;
    if (q > 0 && a != 0) {
        // code for handling two roots
    }
    else if (q == 0) {
        x = (-b) / (2 * a);
    }
    else {
        // code for handling no roots
    }
}
```

9

What is relevant in here is the program structure – the failure occurs only if a specific condition is true and a specific branch is taken.

# Control Flow Graph

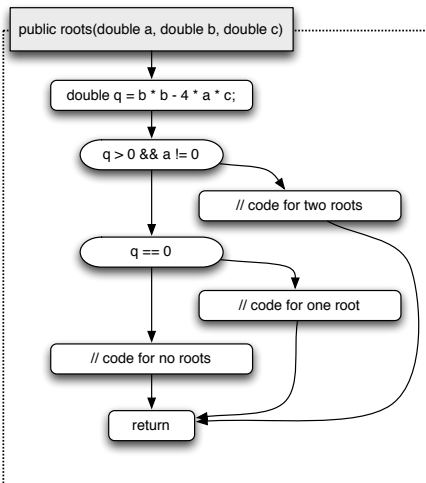

- A *control flow graph* expresses paths of program execution
- Nodes are *basic blocks* – sequences of statements with one entry and one exit point
- Edges represent *control flow* – the possibility that the program execution proceeds from the end of one basic block to the beginning of another

10

To express structure, we turn the program into a *control flow graph*, where statements are represented as nodes, and edges show the possible control flow between statements.

# Structural Testing

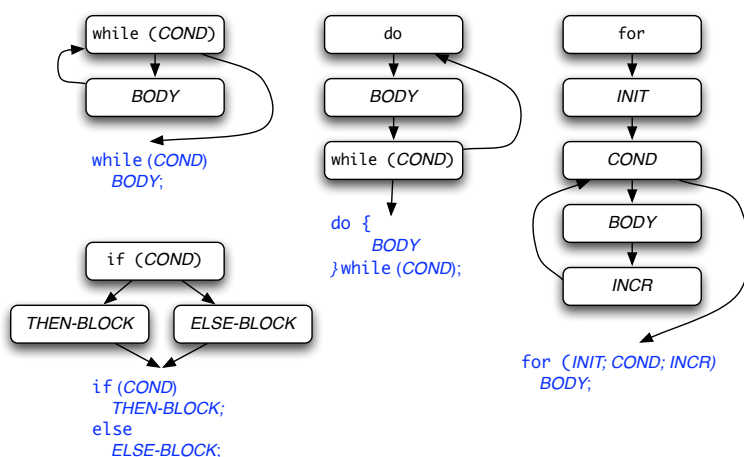

- The CFG can serve as an *adequacy criterion* for test cases
- The more parts are covered (executed), the higher the chance of a test to uncover a defect
- “parts” can be: nodes, edges, paths, conditions...

11

To talk about structure, we turn the program into a *control flow graph*, where statements are represented as nodes, and edges show the possible control flow between statements.

# Control Flow Patterns

12

Every part of the program induces its own patterns in the CFG.

# cgi\_decode

```
/**
 * @title cgi_decode
 * @desc
 * Translate a string from the CGI encoding to plain ascii text
 * '+' becomes space, %xx becomes byte with hex value xx,
 * other alphanumeric characters map to themselves
 *
 * returns 0 for success, positive for erroneous input
 * 1 = bad hexadecimal digit
 */

int cgi_decode(char *encoded, char *decoded)
{
    char *eptr = encoded;
    char *dptr = decoded;
    int ok = 0;
```

13

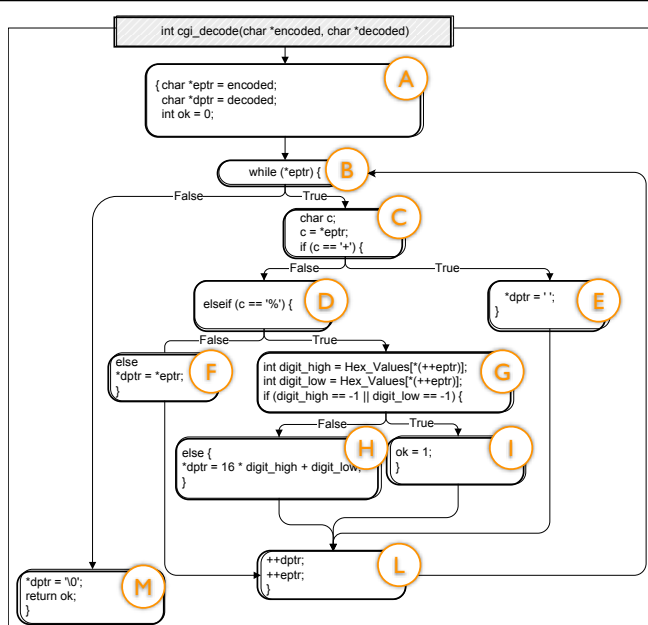

Here's an ongoing example. The function `cgi_decode` translates a CGI-encoded string (i.e., from a Web form) to a plain ASCII string, reversing the encoding applied by the common gateway interface (CGI) on common Web servers.

(from Pezze + Young, "Software Testing and Analysis", Chapter 12)

```
while (*eptr) /* loop to end of string ('\0' character) */
{
    char c;
    c = *eptr;
    if (c == '+') { /* '+' maps to blank */
        *dptr = ' ';
    } else if (c == '%') { /* '%xx' is hex for char xx */
        int digit_high = Hex_Values[*(++eptr)];
        int digit_low = Hex_Values[*(++eptr)];
        if (digit_high == -1 || digit_low == -1)
            ok = 1; /* Bad return code */
        else
            *dptr = 16 * digit_high + digit_low;
    } else { /* All other characters map to themselves */
        *dptr = *eptr;
    }
    ++dptr; ++eptr;
}

*dptr = '\0'; /* Null terminator for string */
return ok;
}
```

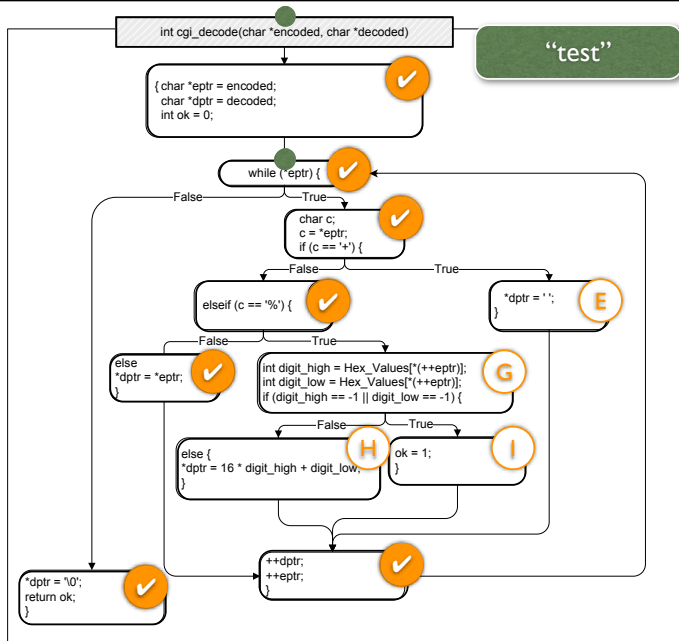

14

15

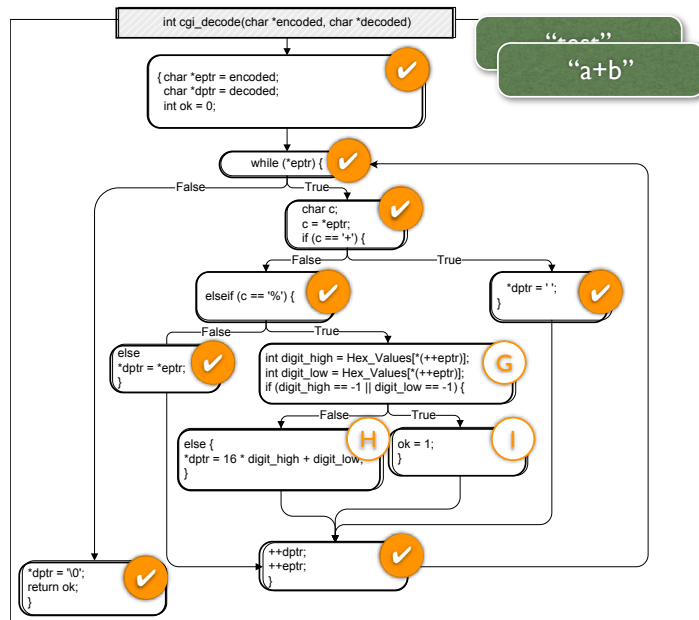

This is what `cgi_decode` looks as a CFG.

(from Pezze + Young, "Software Testing and Analysis", Chapter 12)

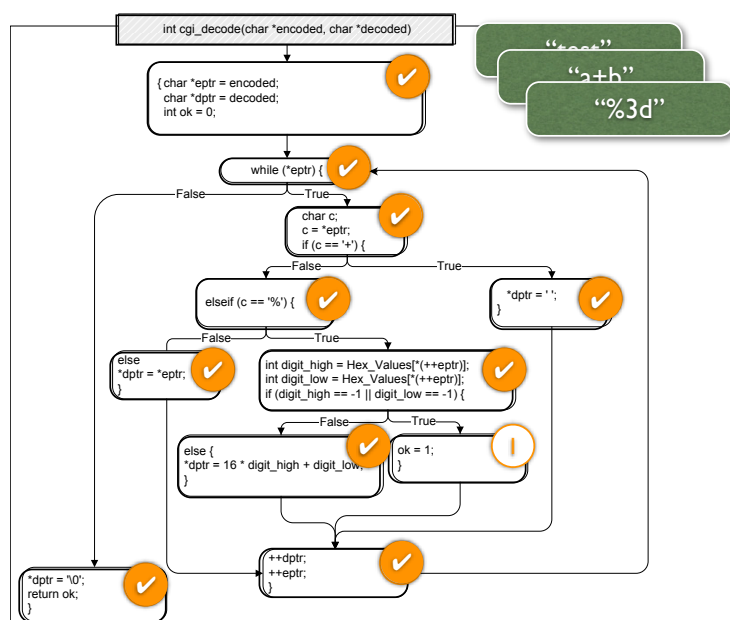

While the program is executed, one statement (or basic block) after the other is covered – i.e., executed at least once – but not all of them. Here, the input is “test”; checkmarks indicate executed blocks.

16

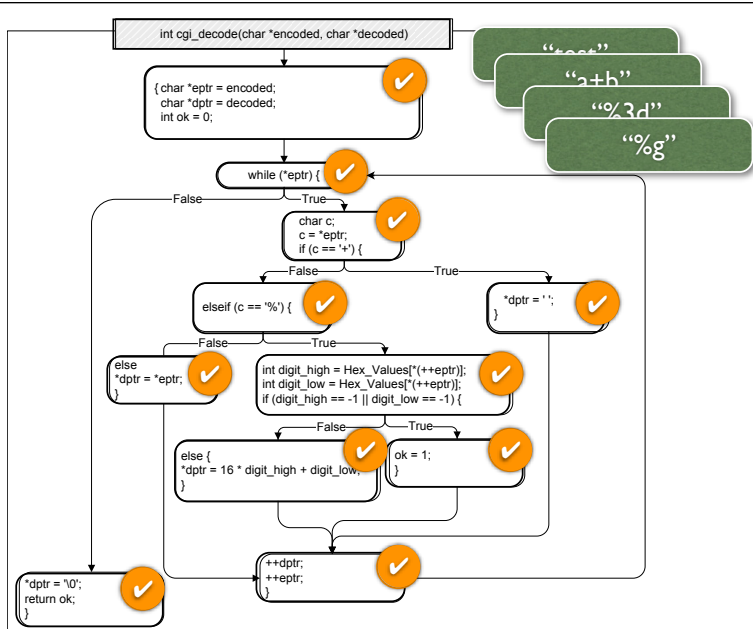

We’d like to test every statement, so we come up with more test cases.

17

We’d like to test every statement, so we come up with more test cases.

18

This is an interesting boundary test case, as it may cause non-deterministic behavior. Can you see why?

19

## Test Adequacy Criteria

- How do we know a test suite is “good enough”?
- A *test adequacy criterion* is a predicate that is true or false for a pair  $\langle \text{program}, \text{test suite} \rangle$
- Usually expressed in form of a rule – e.g., “all statements must be covered”

20

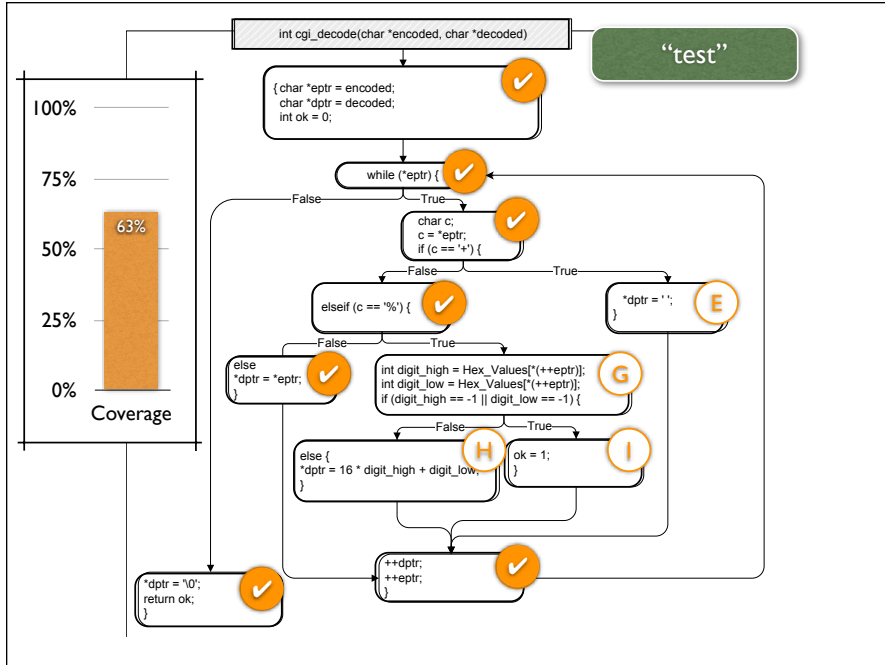

## Statement Testing

- Adequacy criterion: each statement (or node in the CFG) must be executed at least once
- Rationale: a defect in a statement can only be revealed by executing the defect
- Coverage:  $\frac{\# \text{ executed statements}}{\# \text{ statements}}$

(from Pezze + Young, “Software Testing and Analysis”, Chapter 12)

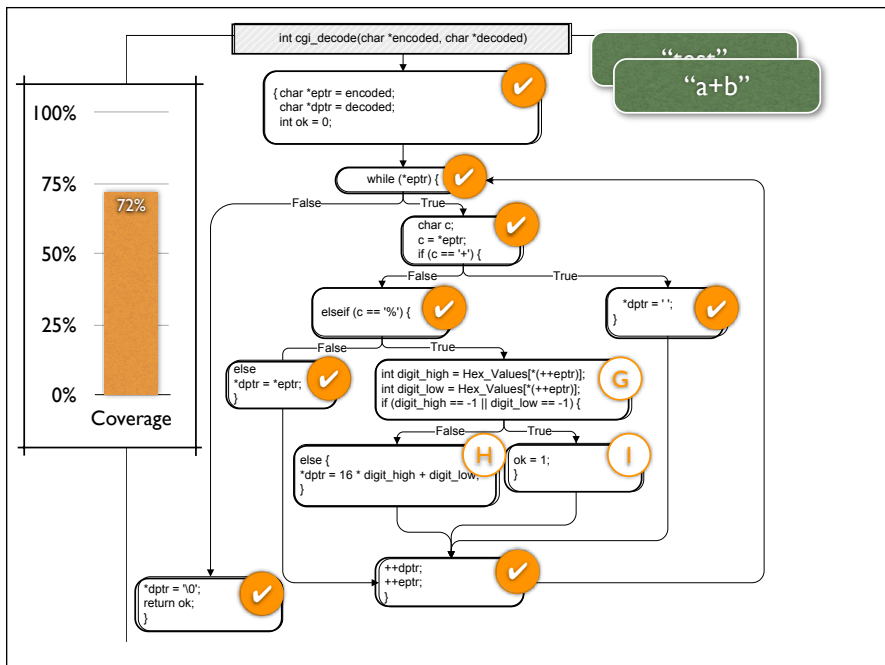

21

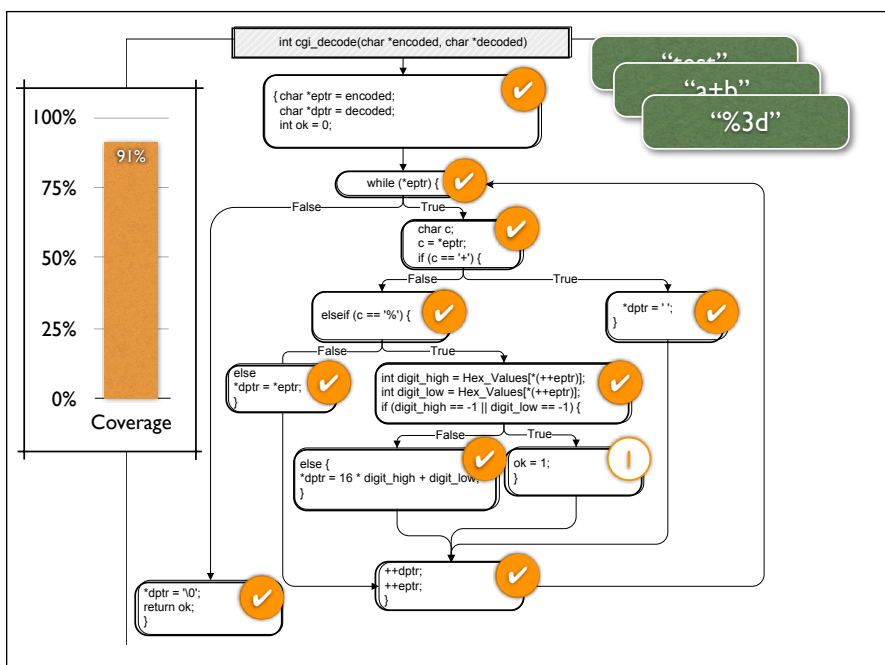

The initial coverage is 7/11 blocks = 63%. We could also count the statements instead (here: 14/20 = 70%), but conceptually, this makes no difference.

22

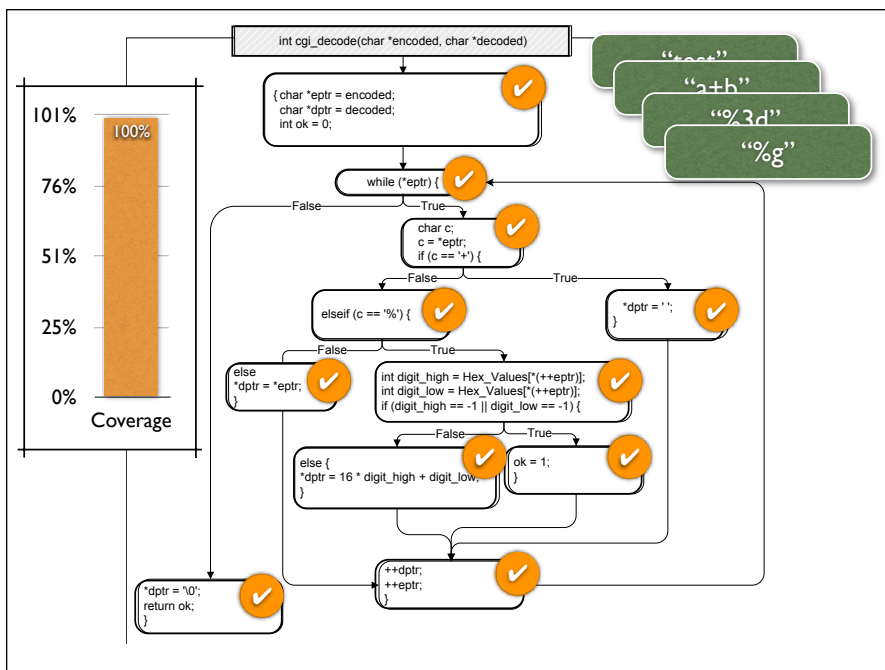

and the coverage increases with each additionally executed statement...

23

24

... until we reach 100% block coverage (which is 100% statement coverage, too).

25

For Java, use jcoverage or like tools.

## Computing Coverage

- Coverage is computed automatically while the program executes
- Requires *instrumentation* at compile time  
With GCC, for instance, use options `-ftest-coverage -fprofile-arcs`
- After execution, *coverage tool* assesses and summarizes results  
With GCC, use “`gcov source-file`” to obtain readable `.gcov` file

26

```

Pippin: cgi_encode — less — 80x24
 4: 18:   int ok = 0;
-: 19:
38: 20:   while (*eptr) /* loop to end of string ('\0' character) */
-: 21:   {
-: 22:       char c;
30: 23:       c = *eptr;
30: 24:       if (c == '+') { /* '+' maps to blank */
1: 25:         *dptr = ' ';
29: 26:       } else if (c == '%') { /* '%xx' is hex for char xx */
3: 27:         int digit_high = Hex_Values[*(++eptr)];
3: 28:         int digit_low = Hex_Values[*(++eptr)];
5: 29:         if (digit_high == -1 || digit_low == -1)
2: 30:             ok = 1; /* Bad return code */
-: 31:         else
1: 32:             *dptr = 16 * digit_high + digit_low;
-: 33:         } else { /* All other characters map to themselves */
26: 34:             *dptr = *eptr;
-: 35:         }
30: 36:         ++dptr; ++eptr;
-: 37:     }
4: 38:     *dptr = '\0'; /* Null terminator for string */
4: 39:     return ok;
-: 40: }

```

This is the output of the GCOV coverage tool for `cgi_decode`. Each statement (each line) is annotated with the number of executions so far. Zero executions is suspicious and would be marked by “#####”; the tag “—” stands for lines without executable code.

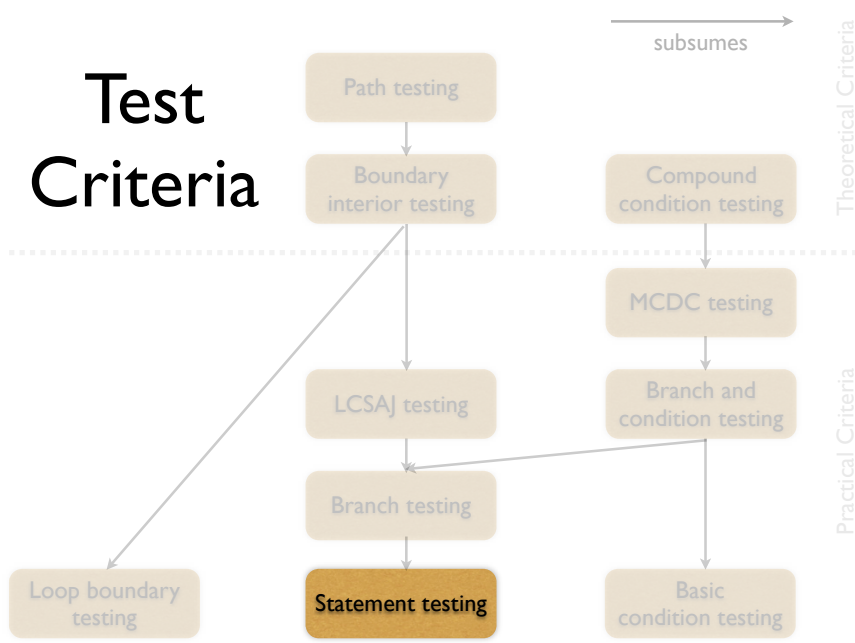

27

# Demo

See the package “cgi\_decode.zip” on the course page for instructions on how to do this yourself.

28

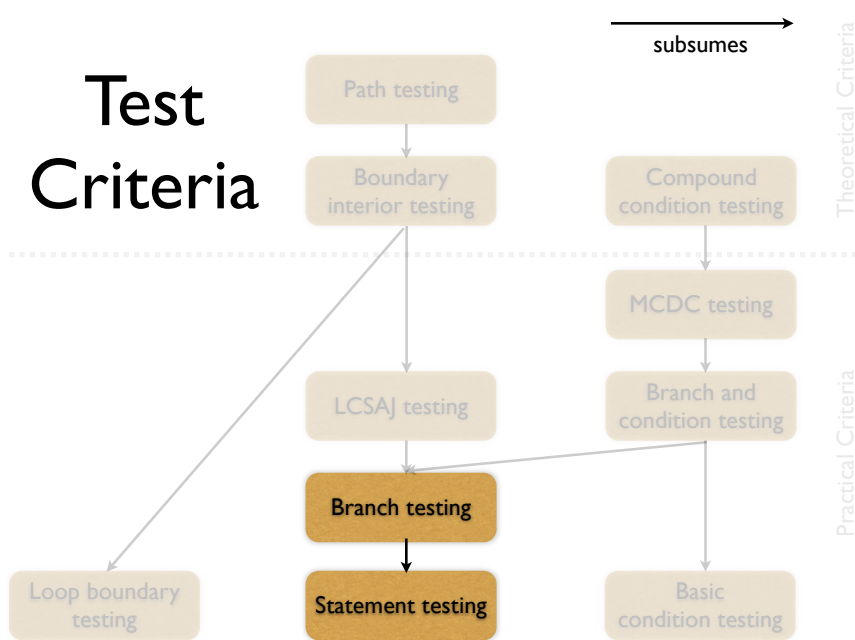

## Test Criteria

Statement testing is a simple criterion for assessing the adequacy of a test suite – but there are many more such criteria.

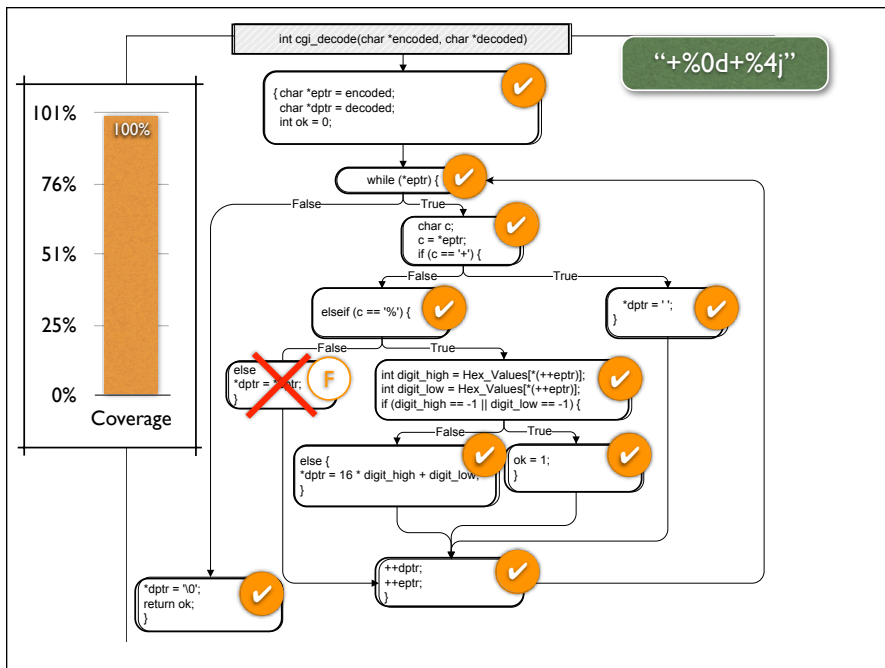

29

## Test Criteria

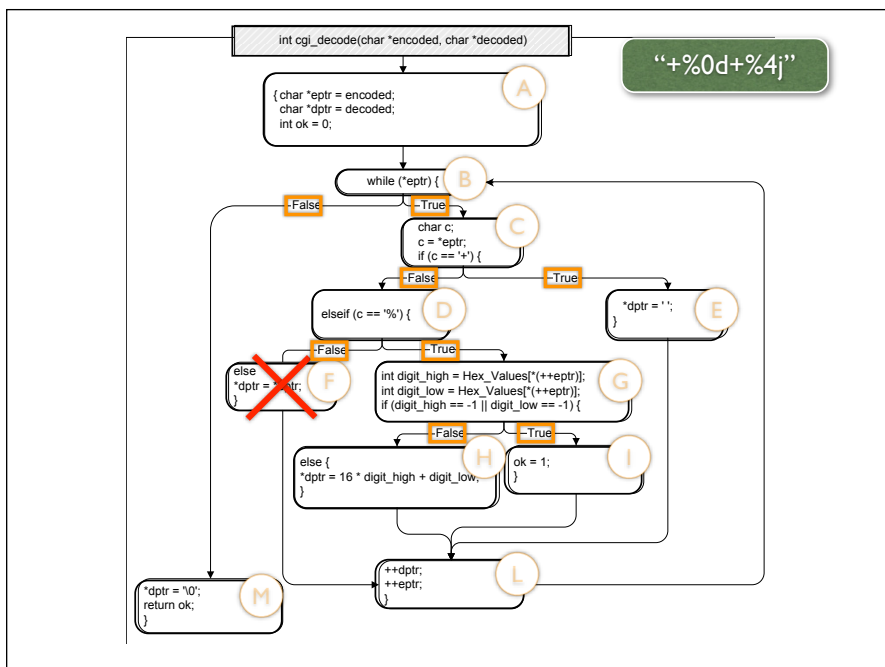

As an example, consider branch testing, which is a criterion that subsumes statement testing. In other words, if the branch testing criterion is satisfied by a pair  $\langle \text{program}, \text{test suite} \rangle$ , so is the statement testing criterion for the same pair.

30

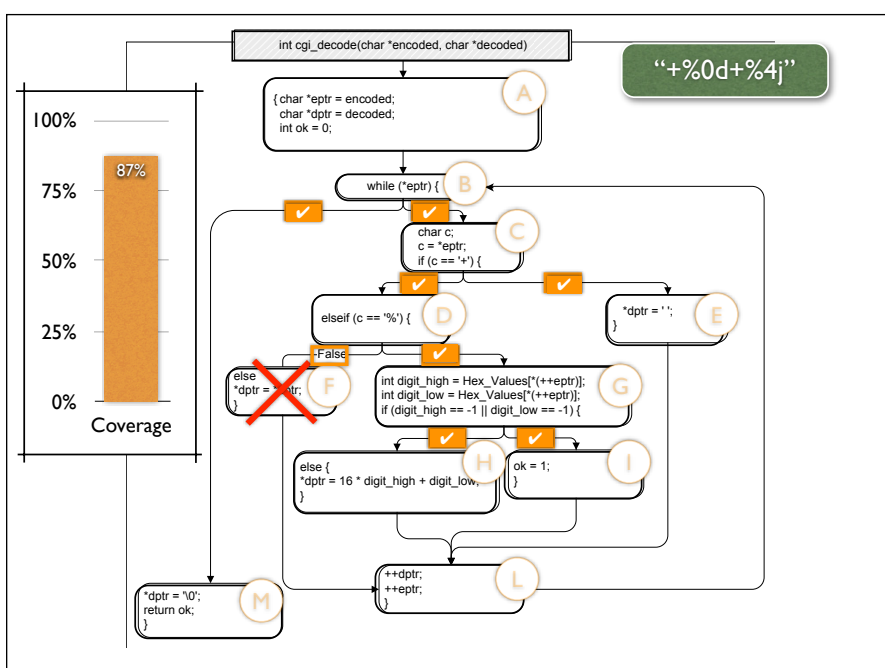

Why is branch testing useful? Assume block F were missing (= a defect). Then, we could achieve 100% statement coverage without ever triggering the defect.

31

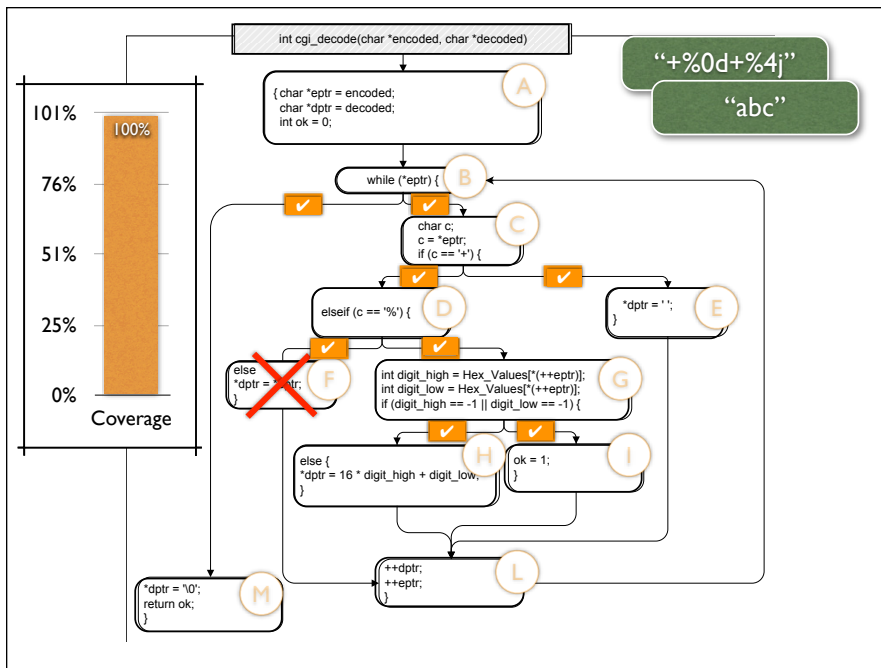

If we focus on whether branches have been taken, though, we get a different picture.

32

Here, we'd find that the test case executes only 7 out of 8 branches, or 87%.

33

With another test case, we can cover this remaining branch – and find the defect.

34

## Branch Testing

- Adequacy criterion: each branch in the CFG must be executed at least once
- Coverage:  $\frac{\# \text{executed branches}}{\# \text{branches}}$
- Subsumes statement testing criterion because traversing all edges implies traversing all nodes
- Most widely used criterion in industry

(from Pezze + Young, "Software Testing and Analysis", Chapter 12)

35

## Condition Testing

- Consider the defect  
`(digit_high == 1 || digit_low == -1)`  
`// should be -1`
- Branch adequacy criterion can be achieved by changing only `digit_low`  
i.e., the defective sub-expression may never determine the result
- Faulty sub-condition is never tested  
although we tested both outcomes of the branch

36

# Condition Testing

- Key idea: also cover *individual conditions* in compound boolean expression  
e.g., both parts of `digit_high == 1 || digit_low == -1`

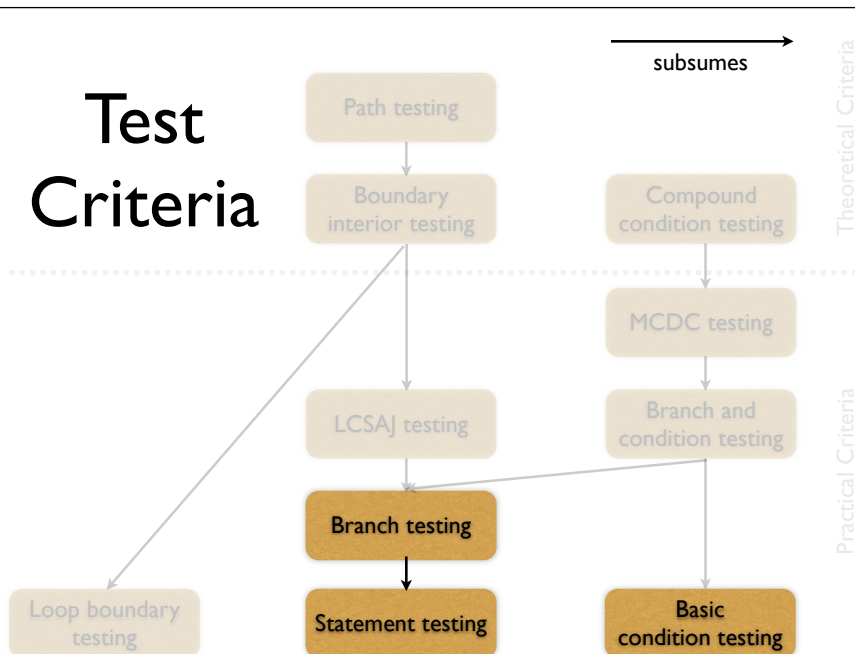

37

# Condition Testing

- Adequacy criterion: each basic condition must be evaluated at least once
- Coverage:  
$$\frac{\# \text{ truth values taken by all basic conditions}}{2 * \# \text{ basic conditions}}$$
- Example: `"test+%9k%k9"`  
100% basic condition coverage  
but only 87% branch coverage

38

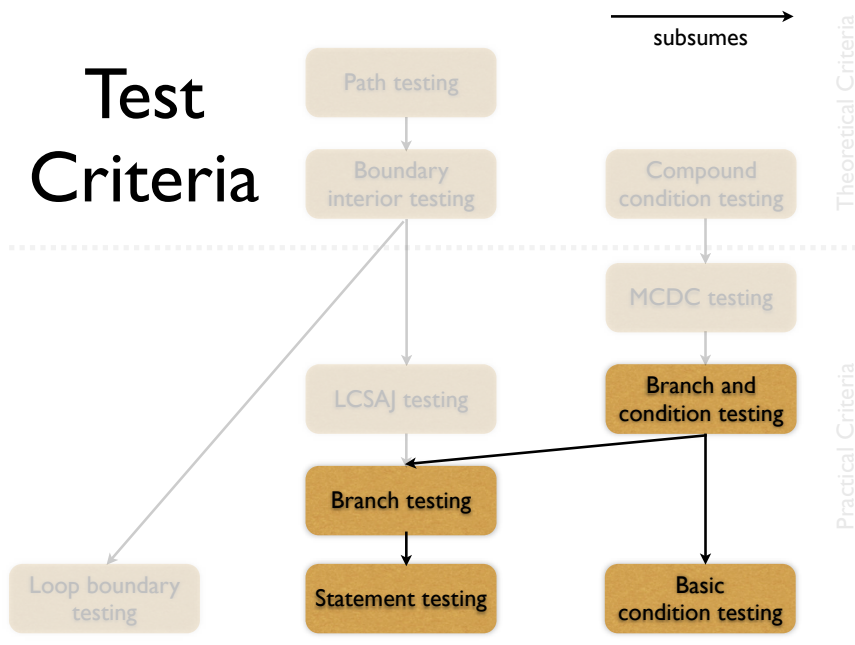

## Test Criteria

The basic condition criterion is not comparable with branch or statement coverage criteria – neither implies (subsumes) the other.

39

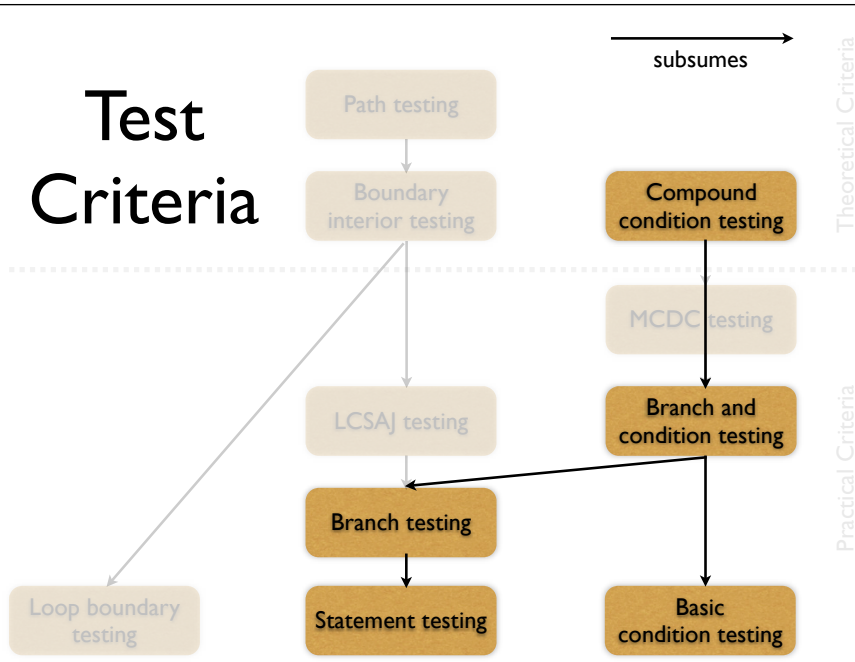

# Test Criteria

The idea here is to cover both branch and condition testing – by covering all conditions and all decisions. That is, every sub-condition must be true and false, but the entire condition just as well.

40

# Test Criteria

Another idea might be simply to test all possible combinations. This is called compound condition testing.

41

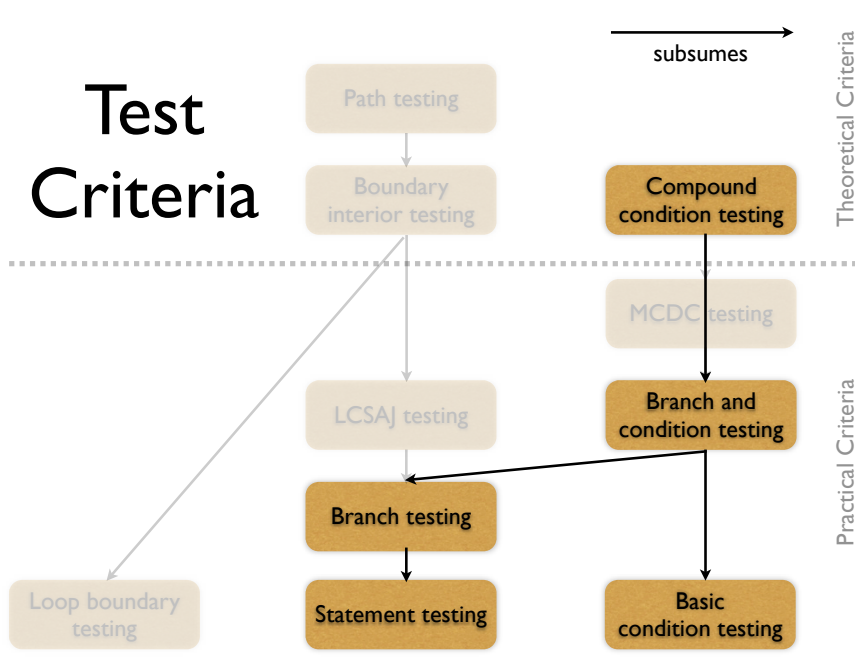

## Compound Conditions

- Assume  $((a \vee b) \wedge c) \vee d) \wedge e)$
- We need 13 tests to cover all possible combinations
- In general case, we get a combinatorial explosion

Test Case	a	b	c	d	e
(1)	True	-	True	-	True
(2)	False	True	True	-	True
(3)	True	-	False	True	True
(4)	False	True	False	True	True
(5)	False	False	-	True	True
(6)	True	-	True	-	False
(7)	False	True	True	-	False
(8)	True	-	False	True	False
(9)	False	True	False	True	False
(10)	False	False	-	True	False
(11)	True	-	False	False	-
(12)	False	True	False	False	-
(13)	False	False	-	False	-

42

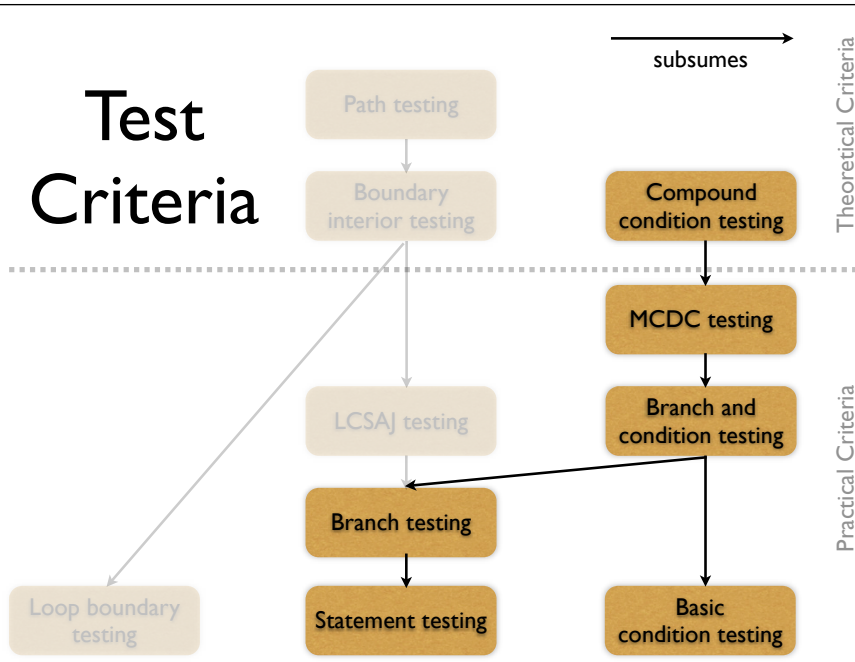

# Test Criteria

The combinatorial explosion is the reason why compound condition testing is a theoretical, rather than a practical criterion.

43

# Test Criteria

A possible compromise is MCDC or Modified Condition/Decision Coverage testing.

44

## MCDC Testing

Modified Condition Decision Coverage

- Key idea: Test *important combinations* of conditions, avoiding exponential blowup
- A combination is “important” if each basic condition is shown to independently affect the outcome of each decision

45

# MCDC Testing

Modified Condition Decision Coverage

- For each basic condition  $C$ , we need two test cases  $T_1$  and  $T_2$
- Values of all *evaluated* conditions except  $C$  are the same
- Compound condition as a whole evaluates to *True* for  $T_1$  and *false* for  $T_2$
- A good balance of thoroughness and test size (and therefore widely used)

46

# MCDC Testing

Modified Condition Decision Coverage

- Assume  $((a \vee b) \wedge c) \vee d) \wedge e)$
- We need six tests to cover MCDC combinations

	a	b	c	d	e	Decision
(1)	<u>True</u>	–	<u>True</u>	–	<u>True</u>	True
(2)	False	<u>True</u>	True	–	True	True
(3)	True	–	False	<u>True</u>	True	True
(6)	True	–	True	–	<u>False</u>	False
(11)	True	–	<u>False</u>	<u>False</u>	–	False
(13)	<u>False</u>	<u>False</u>	–	False	–	False

Underlined values independently affect the outcome of the decision. Note that the same test case can cover the values of several basic conditions. For example, test case (1) covers value True for the basic conditions a, c and e. Note also that this is not the only possible set of test cases to satisfy the criterion; a different selection of boolean combinations could be equally effective.

47

# Path Testing

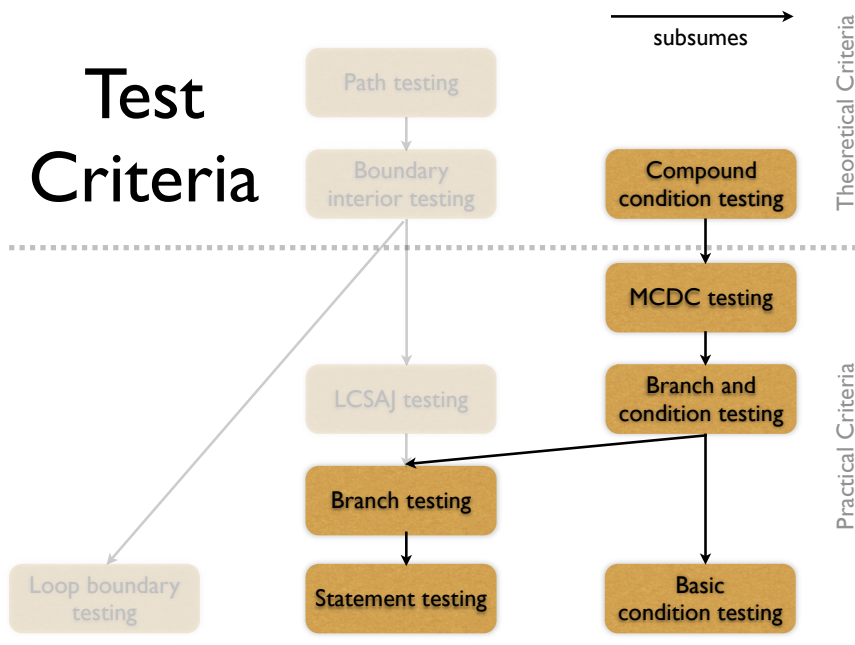

beyond individual branches

- Key idea: explore *sequences of branches* in control flow
- Many more paths than branches  
calls for compromises

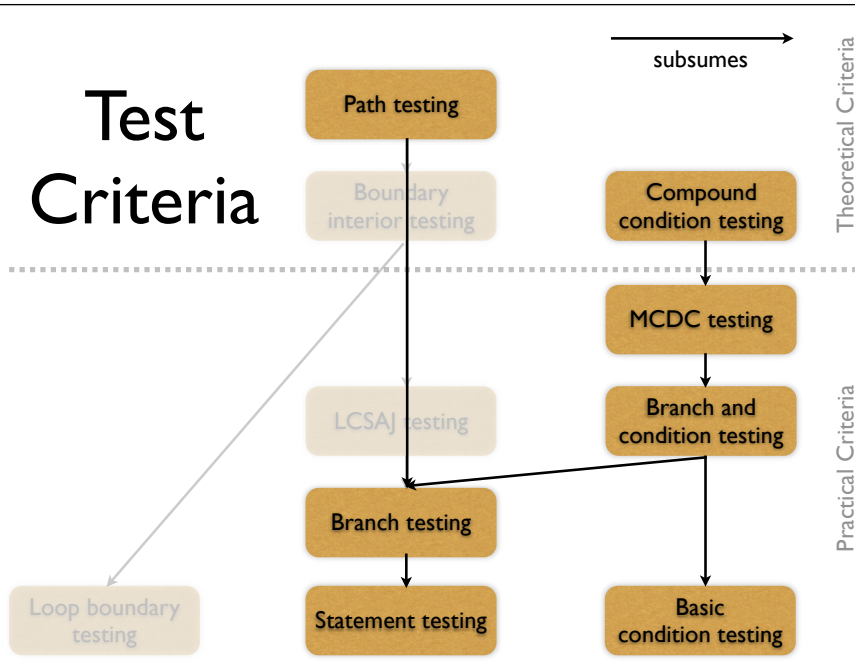

48

# Test Criteria

49

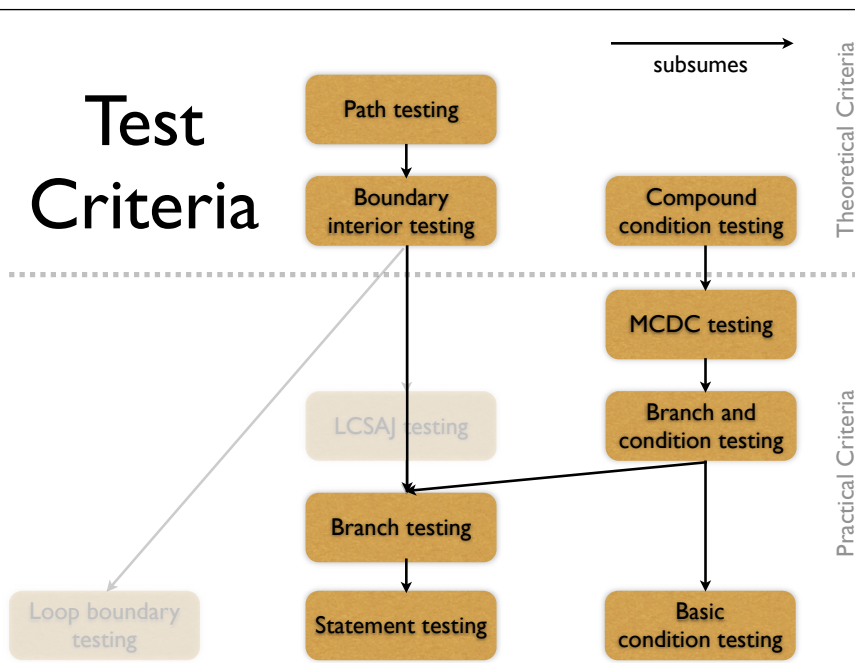

# Test Criteria

50

For one thing, there is general path testing, i.e. covering all paths in the program. Since loops are unbounded, this is generally not feasible and therefore just a theoretical criterion. Its advantage, though, is that it subsumes almost all criteria.

# Test Criteria

51

Boundary interior testing groups together paths that differ only in the subpath they follow when repeating the body of a loop. In other words, we follow each path in the CFG up to the first repeated node.

# Boundary Interior Adequacy

for cgi\_decode

Original CFG

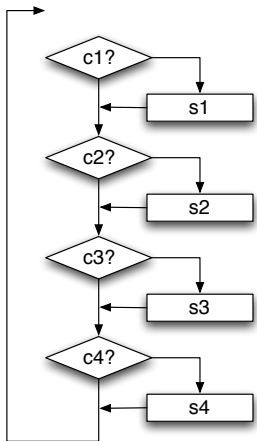

Paths to be covered

The graph at the right shows the paths that must be covered in the control flow graph at the left, using the “boundary interior” adequacy criterion.

52

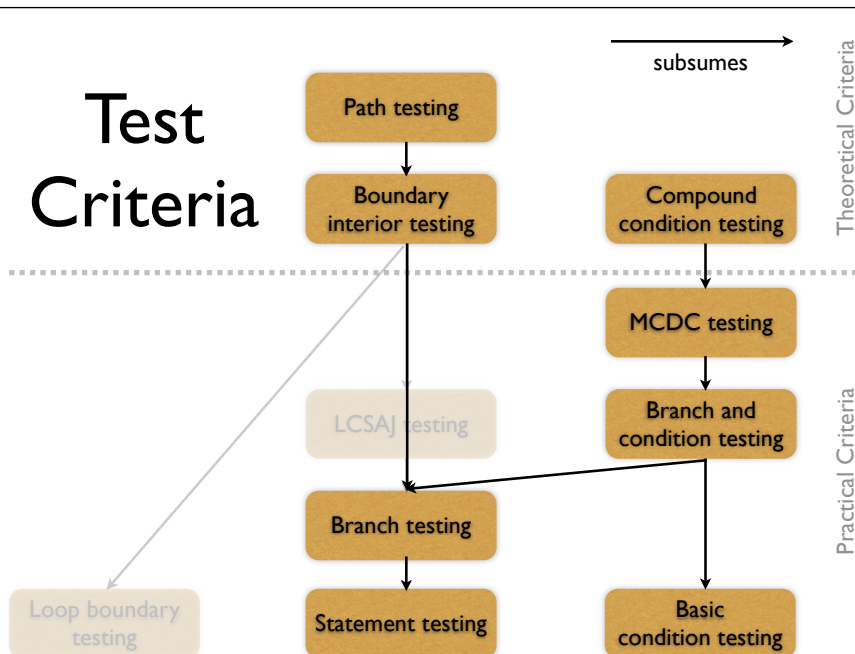

## Issues

- The number of paths may still grow exponentially  
In this example, there are  $2^4 = 16$  paths
- Forcing paths may be *infeasible* or even *impossible* if conditions are not independent

53

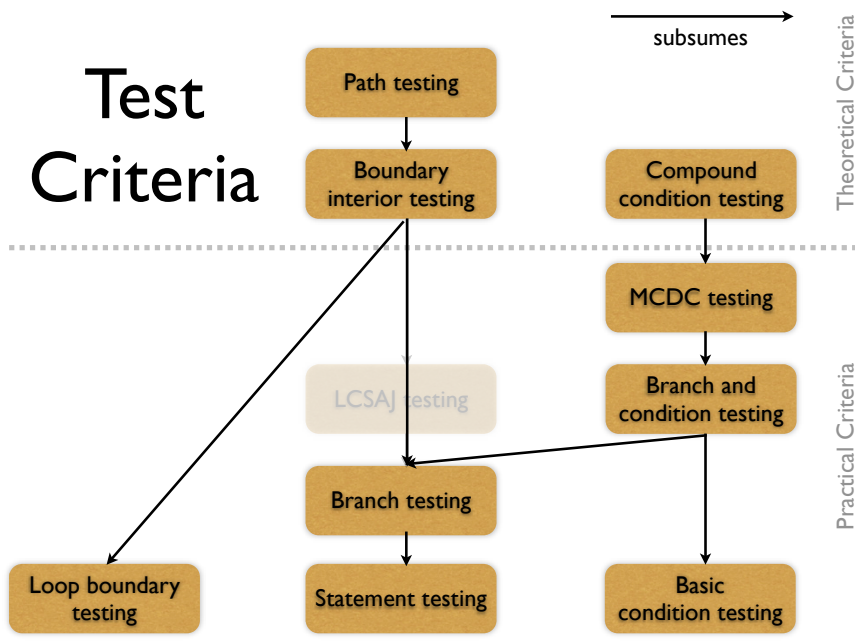

## Test Criteria

Therefore, boundary interior testing belongs more to the “theoretical” criteria.

54

# Test Criteria

55

Another alternative is loop boundary testing which forces constraints on how loops are to be executed. This is a practical criterion.

## Loop Boundary Adequacy

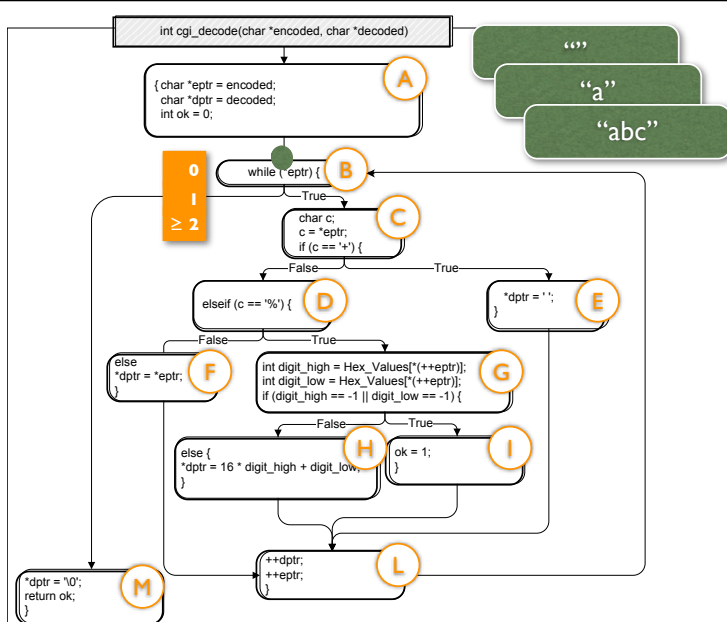

A test suite satisfies the loop boundary adequacy criterion if for every loop  $L$ :

- There is a test case which iterates  $L$  zero times
- There is a test case which iterates  $L$  once
- There is a test case which iterates  $L$  more than once

Typically combined with other adequacy criteria such as MCDC

This is a variant of the boundary/interior criterion that treats loop boundaries similarly but is less stringent with respect to other differences among paths

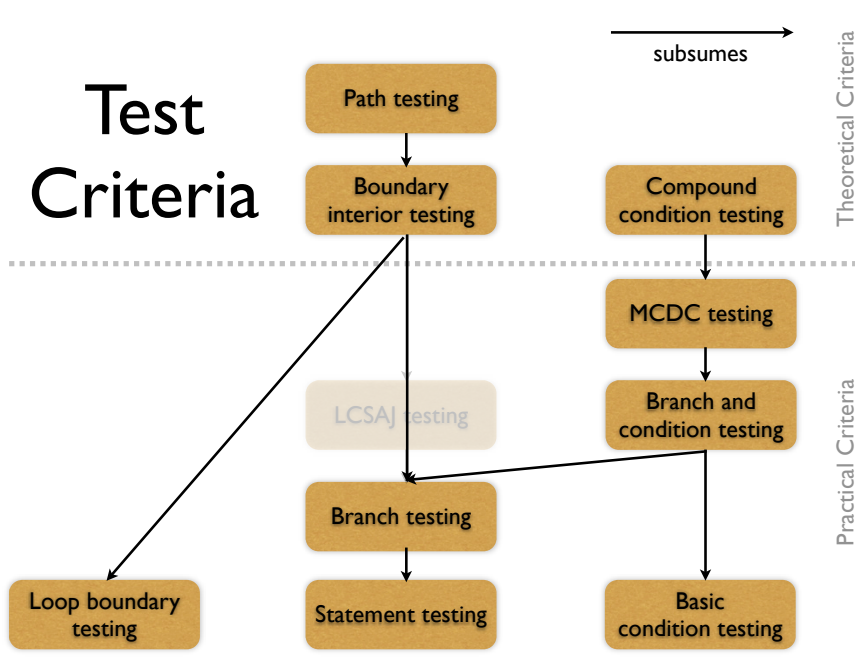

56

57

With these three test cases, we obtain loop boundary adequacy for the cgi\_decode main loop.

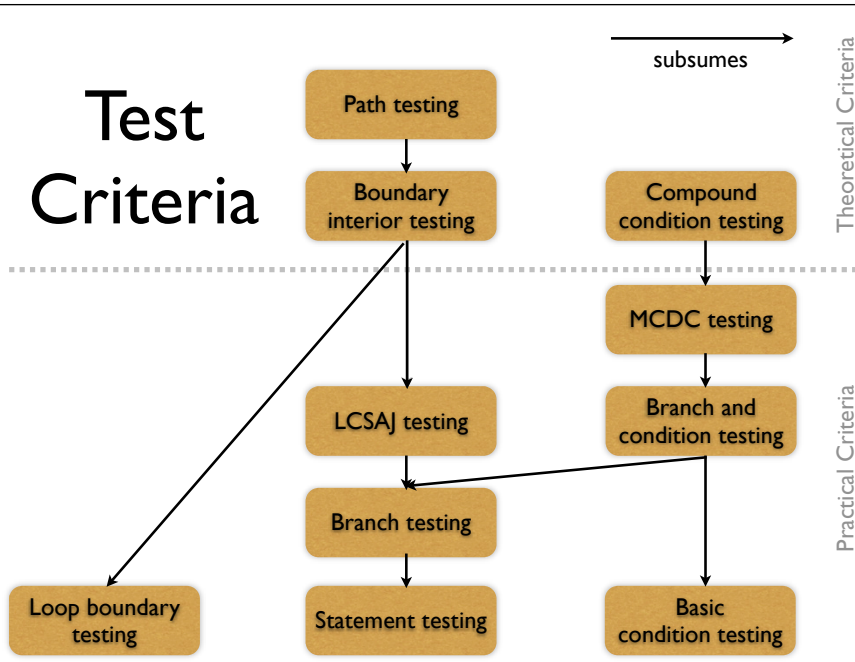

# Test Criteria

Another alternative is loop boundary testing which forces constraints on how loops are to be executed.

58

# Test Criteria

LCSAJ is a generalization over branch and statement coverage.

59

## LCSAJ Adequacy

Testing all paths up to a fixed length

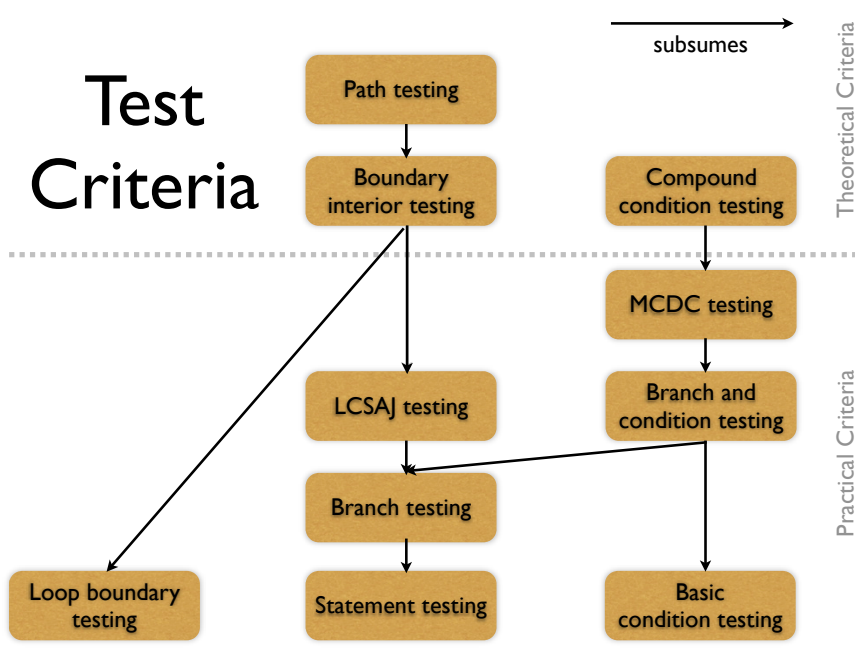

- LCSAJ = Linear Code Sequence And Jump
- A LCSAJ is a sequential subpath in the CFG starting and ending in a branch

LCSAJ length	corresponds to
1	statement coverage
2	branch coverage
$n$	coverage of $n$ consecutive LCSAJs
$\infty$	path coverage

Considering the exponential blowup in sequences of conditional statements (even when not in loops), we might choose to consider only sub-sequences of a given length. This is what LCSAJ gives us --- essentially considering full path coverage of (short) sequences of decisions.

60

# Test Criteria

And this is the summary of structural testing techniques.

61

## Weyuker's Hypothesis

The adequacy of a coverage criterion can only be intuitively defined.

Established by a number of studies done by E. Weyuker at AT&T. "Any explicit relationship between coverage and error detection would mean that we have a fixed distribution of errors over all statements and paths, which is clearly not the case".

62

## Satisfying Criteria

Sometimes criteria may not be satisfiable:

- *Statements* may not be executed because of *defensive programming* or *code reuse*
- *Conditions* may not be satisfiable because of *interdependent conditions*
- *Paths* may not be executable because of *interdependent decisions*

63

# Satisfying Criteria

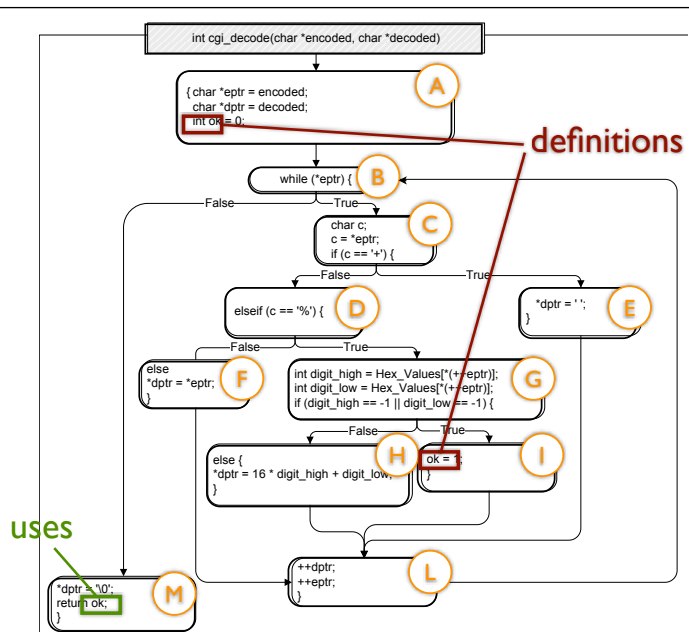

- Reaching specific code can be very hard!
- Even the best-designed, best-maintained systems may contain unreachable code
- A large amount of unreachable code/paths/conditions is a serious *maintainability problem*
- Solutions: allow coverage less than 100%, or require justification for exceptions

64

## More Testing Criteria

- Object-oriented testing  
e.g., “Every transition in the object’s FSM must be covered” or “Every method pair in the object’s FSM must be covered”
- Interclass testing  
e.g., “Every interaction between two objects must be covered”
- Data flow testing  
e.g., “Every definition-use pair of a variable must be covered”

65

66

Data flow testing is based on the observation that computing the wrong value leads to a failure only when that value is subsequently used. A typical data flow testing criterion is therefore that the tests must exercise every pair (definition, uses) of a variable (such as “ok” in this example).

## Testing Tactics

- Tests based on spec
- Test covers as much specified behavior as possible
- Tests based on code
- Test covers as much implemented behavior as possible

## Control Flow Graph

- A control flow graph expresses paths of program execution
- Nodes are basic blocks – sequences of statements with one entry and one exit point
- Edges represent control flow – the possibility that the program execution proceeds from the end of one basic block to the beginning of another

# Summary
